

Case Study #2 – SAP Customer Service Process Transition & Improvement

Project Overview

This portfolio case study simulates the role of an Application Process Manager supporting the transition and improvement of an existing Salesforce-based Customer Service process toward an integrated SAP service landscape.

The objective was not simply to replace one application with another, but to analyze the existing end-to-end process, identify improvement opportunities, define the future process, translate business needs into requirements, manage representative changes through Jira, validate them through UAT scenarios, and prepare a controlled release and post-go-live approach.

Target Landscape

The conceptual target landscape consists of:

Customer Portal → SAP Service Cloud ↔ SAP S/4HANA

When physical on-site work is required:

SAP Service Cloud → Field Service Process → Dispatcher/Planner → Field Technician → Service Result → SAP Backend / Customer Service Case

SAP Service Cloud represents the customer-service and case-management layer, while SAP S/4HANA provides relevant ERP/backend information and processes.

Field Service is triggered only when physical inspection, repair, replacement or another on-site activity is required.

My Role in the Case Study

Acting from an Application Process Manager perspective, I:

- Defined the business context, objectives and scope.
 - Identified key business and IT stakeholders.
 - Analyzed the existing Salesforce-based AS-IS process.
 - Modelled the AS-IS process using BPMN in SAP Signavio.
 - Performed a Fit-Gap Analysis.
 - Identified and prioritized process-improvement opportunities.
 - Designed the future SAP-supported TO-BE process.
 - Modelled the TO-BE process in SAP Signavio.
 - Defined business and functional requirements.
 - Established traceability between process gaps and requirements.
 - Created an Epic and representative change Stories in Jira.
 - Defined acceptance criteria using Given-When-Then.
 - Created UAT scenarios and expected results.
 - Defined a high-level release and implementation approach.
 - Defined stakeholder communication and hypercare activities.
 - Identified potential post-go-live KPIs.
-

AS-IS Process

The existing process uses a customer-facing portal connected to Salesforce for service-case management.

The high-level process includes:

Customer Request → Case Creation → Information Review → Categorization/Priority → Assignment → Investigation → Remote Diagnosis

If remotely resolvable:

Remote Solution → Resolution → Customer Communication → Case Closure

If on-site intervention is required:

Field Service Handover → Dispatcher/Planner → Technician Scheduling → On-Site Service → Service Result → Customer Service → Closure

The AS-IS process is operational but presents opportunities for greater standardization and integration.

Key Improvement Opportunities

The analysis identified opportunities including:

- Incomplete information at service-request creation.
 - Manual clarification loops.
 - Incorrect case assignment and manual reassignment.
 - Inconsistent categorization and prioritization.
 - Non-standardized remote-versus-field-service decisions.
 - Incomplete Field Service handovers.
 - Repeated clarification before technician planning.
 - Limited end-to-end Field Service status visibility.
 - Manual service-result communication.
 - Inconsistent closure criteria.
 - Opportunities for stronger process KPI monitoring.
-

TO-BE Process Improvements

The proposed future process introduces:

- Mandatory-information validation.
- Standardized case categories.
- Defined priority rules.
- Rule-based case routing.
- Improved access to relevant customer/equipment/service information.
- Standardized remote-diagnosis documentation.
- Defined Field Service decision criteria.

- Structured Field Service handover.
 - Field Service readiness validation.
 - Structured Field Service status and result feedback.
 - Standardized resolution and closure criteria.
 - Improved process monitoring.
-

Requirements Management

Business needs were translated into Business Requirements and Functional Requirements.

A traceability model was maintained:

AS-IS Observation → Fit-Gap → Business Requirement → Functional Requirement → Jira Story → Acceptance Criteria → UAT

Example:

AS-IS Issue: Incorrect assignment/manual reassignment

↓

FG-05: Case Routing Gap

↓

BR-04: Cases should reach the appropriate responsible team

↓

FR-05: Solution shall support routing based on defined business criteria

↓

SCSI-9: Implement standardized case routing

↓

Acceptance Criteria: Category-based routing behavior

↓

UAT-02: Create a categorized case and verify assignment to the expected team

Jira Change Management

A Jira project was created to simulate application-change management.

Epic:

SAP Customer Service Process Transition & Improvement

Representative Stories covered:

1. Mandatory service-request information
2. Standardized case routing
3. Remote-versus-Field-Service decision
4. Field Service handover/readiness
5. Field Service status/result visibility
6. Standardized service-case closure

A representative Story was documented with business context, traceability, business value and Given-When-Then acceptance criteria.

UAT

Representative UAT scenarios were created for the selected requirements.

Testing covered:

- Mandatory-information validation
- Case routing
- Remote/Field Service decision
- Field Service handover readiness
- Field Service status/result visibility
- Case-closure validation

The case study uses simulated UAT execution/results to demonstrate the methodology. No productive SAP environment was tested.

Release & Implementation

The release approach covers:

Requirements Approval → Implementation → Testing → UAT → Business Approval → Deployment → Validation → Hypercare → Normal Operations

Activities include release-readiness checks, stakeholder communication, documentation, business validation, deployment coordination, post-go-live support and KPI monitoring.

Technical deployment is assumed to be performed by the responsible SAP technical, functional and release teams.

Tools Used

SAP Signavio

- BPMN process modelling
- AS-IS process visualization
- TO-BE process visualization

Jira

- Epic and Story management
- Change tracking
- Prioritization
- Acceptance criteria
- Workflow/status tracking

Microsoft Excel

- Fit-Gap Analysis
- Improvement analysis
- UAT test cases

Microsoft Word

- Business/process documentation

- Requirements documentation
- Release/implementation documentation

SAP Landscape Concepts

- SAP Service Cloud
 - SAP S/4HANA
 - Field Service integration
-

Key Skills Demonstrated

- Business Process Analysis
 - Application Process Management
 - AS-IS / TO-BE Analysis
 - BPMN
 - SAP Signavio
 - Fit-Gap Analysis
 - Requirements Engineering
 - Business Requirements
 - Functional Requirements
 - Jira Change Management
 - Acceptance Criteria
 - UAT
 - Stakeholder Management
 - Release Coordination
 - Process Improvement
 - SAP Customer Service Process Understanding
 - Cross-functional Business/IT Coordination
-

Case Study Disclaimer

This is a self-developed portfolio case study designed to demonstrate Application Process Management methodology.

It is not a productive SAP implementation and does not represent employment-based implementation experience.

The SAP landscape, requirements, Jira workflow, UAT execution and release activities are simulated to demonstrate understanding of an end-to-end application/process change lifecycle.
